# 1. Introduction

Democritus is a programming language with a static type system and native support for concurrent programming via its atomic keyword, with facilities for both imperative and functional programming. Democritus is compiled to the LLVM (Low Level Virtual Machine) intermediate form, which can then be optimized to machine-specific assembly code. Democritus' syntax draws inspiration from contemporary languages, aspiring to emulate Go and Python in terms of focusing on use cases familiar to the modern software engineer, emphasizing readability, and having "one – and preferably only one – obvious way to do it".

### 1.1 Motivation

The main motivation behind Democritus was to create a lower level imperative language that supported concurrency 'out-of-the-box'. The race condition arising from threading would be solved by the language's atomic keyword, which provides a native locking system for variables and data. Users would then be able to write and run simple multi-threaded applications relatively quickly.

## 1.2 Product Goals

### **Native Concurrency and Atomicity**

Users should be able to easily and quickly thread their program with minimal worry about race conditions. Their development process would not be hindered by the use of multithreading, nor should they have to define special threading classes as is common in some other languages.

### Portability

Developed under the LLVM IR, code written in Democritus can be compiled and run on any machine that LLVM can run on. As an industrial-level compiler, LLVM offers robustness and portability as the compiler back-end of Democritus.

## Flexibility

Though Democritus is not an object-oriented language, it seeks to grant users flexibility in functionality, supporting structures, standard primitive data types, and native string support.

<sup>&</sup>lt;sup>1</sup>http://c2.com/cgi/wiki?PythonPhilosophy

# 2. Language Tutorial

Democritus is a strongly-typed, imperative language with standard methods for conditional blocks, iteration, variable assignment, and expression evaluation. In this chapter, we will cover environment configuration as well as utilizing Democritus' basic and more advanced features.

# 2.1 Setup and Installation

To set up the Democritus compiler, OCaml and LLVM must be installed. Testing and development was done in both native Ubuntu 15.04 and Ubuntu 14.04 running on a virtual machine.

```
sudo apt-get install m4 clang-3.7 clang-3.7-doc libclang-common-3.7-dev libclang-3.7-dev libclang1-3.7-dbg libllvm-3.7-ocaml-dev libllvm3.7 libllvm3.7-dbg lldb-3.7 llvm-3.7 llvm-3.7-dev llvm-3.7-doc llvm-3.7-examples llvm-3.7-runtime clang-modernize-3.7 clang-format-3.7 python-clang-3.7 lldb-3.7-dev liblldb-3.7-dbg opam llvm-runtime
```

For Ubuntu 15.04, we need the matching LLVM 3.6 OCaml Library.

```
sudo apt-get install -y ocaml m4 llvm opam
opam init
opam install llvm.3.6 ocamlfind
eval 'opam config env'
```

#### For Ubuntu 14.04:

```
sudo apt-get install m4 llvm software-properties-common

sudo add-apt-repository —yes ppa:avsm/ppa
sudo apt-get update -qq
sudo apt-get install -y opam
opam init

eval 'opam config env'

opam install llvm.3.4 ocamlfind
```

After setting up the environment, clone the git repository into your desired installation directory:

```
git clone https://github.com/DemocritusLang/Democritus.git
```

# 2.2 Compiling Your Code

To build the compiler, cd into the Democritus repository, and run make.

If building fails, try running eval 'opam config env', which should update your local environment use OPAM packages and compilers. It's recommended to add the above command to your shell's configuration file if you plan on developing with Democritus.

To compile code, simply run

```
./Democritus < filename.demo > outfile.lli
```

To run compiled code, call 11i on the output:

```
lli outfile.lli
```

# 2.3 Writing Code

Code can be written in any text file, but Democritus source files should have the .dem extension by convention. Democritus programs consist of global function, struct, and variable declarations. Only the code inside main() will be exectued at runtime. At this time, linking is not included in the Democritus compiler; all code should be written and compiled from a single .demo source file.

# 2.4 Getting Started

### **Declarations**

Functions are declared with the <function func\_name(a type, b type) return\_type> syntax. Variables are declared with the <let var\_name var\_type;> syntax. Statements are terminated with the semicolon;. Note that all variable declarations must happen before statements (including assignments) in any given function.

```
function triangle_area(base int, height int) int{
  return base*height/2;
}
```

### **Types**

### **Primitives**

Primitive types in Democritus include booleans, integers, and strings. The void type is also used for functions.

```
function main() int{
  let s string;
  let foo int;
  let bar bool;

bar = true;
  s = "Hello, _World!"
  foo = 55;
  bar = false;

return 0;
}
```

#### Structs

Structs are declared at the global level with the <struct struct\_type { named fields }> syntax. Struct declarations may also be nested.

```
struct Person{
  let name string;
  let age int;
  let info struct Info;
struct Info{
 let education string;
 let salary int;
function main() int{
  let p struct Person;
  p.name = "Joe";
  p.age = 30;
  p.info.education = "Bachelor's";
  p.info.salary = 99999;
  print(p.name);
  print("_earns:_");
  print_int(p.info.salary);
  return 0;
```

### **Operators**

Democritus includes the 'standard' set of operators, defined as follows:

### **Binary Operators:**

```
artithmetic: +, -, *, /
logical: ==, !=, <, <=, >, >=, && (and), || (or)
```

### **Unary Operators:**

```
artihmetic: -logical: ! (not)
```

Logical expressions return a boolean value.

The expressions on each side of a binary operation must be of the same type. The &&, ||, and ! operators must be called on boolean expressions.

## 2.5 Control Flow

As an imperative language, Democritus executes statements sequentially from the top of any given function to the bottom. Branching and iteration is done similarly to many other imperative languages.

## **Conditional Branching**

Conditional branching is done with:

```
if(boolean expression)
{
    /* do something here */
}
else
{
    /* do alternative here */
}
```

Here is an example of conditional branching in Democritus:

```
struct Person{
 let education string;
 let name string;
 let age int;
 let working bool;
function main() int{
 let p Struct person;
  p.name = "Joe"
  p.education = "Bachelor's";
  p.age = 25;
  p.working = false;
  if(p.working){
   print(p.name);
   print("_works.\n");
  }else{
   print(p.name);
   print("_is_looking_for_work.\n");
  return 0;
```

## Loops and Iteration

Iteration can be done either via a while or for loop. A while(e1) loop requires e1 to be boolean conditional statement. A for(e1; e2; e3) loop requires three expressions; e1 is called prior to entering the loop, e2 is a boolean conditional statement for the loop, and e3 is called after each iteration. Both e1 and e3 may be empty expressions. Each of the following functions should print 42.

```
function main() int{
  let i int;
  i = 0;
  while(i<42){
    i = i+1;
  }
  print_int(i)
  return 0;</pre>
```

```
function main() int{
  let i int;
  for(i = 0; i<42; i++){
    i = i+1;
  }
  print_int(i)
  return 0;
}</pre>
```

# 2.6 Multithreading and Atomicity

Democritus supports threading with the thread() function call, which then calls the underlying pthread function in C. Any defined function can be called with multiple threads. The calling syntax is as follows:

```
thread("functionname", <comma separated args>, #threads);
```

Multithreaded functions must take a **starvoid** type as input and return a starvoid to conform with C's calling convention. An example of a multithreaded program:

```
function multiprint(noop starvoid) starvoid{
  let x starvoid;
  print("Hello, _World!\n");
  return x;
}

function main() int{
  thread("multiprint", 0, 6); /* "Hello, World!" will be printed six times. */
  return 0;
}
```

## 2.7 Miscellaneous

Besides threading, a couple of other functions from C have been bound to Democritus.

### Malloc

malloc(size) may be called, returning a pointer to a newly heap-allocated block of *size* bytes. These pointers may be bound to strings, which themselves are pointers to string literals. An example utilizing malloc will be included with file I/O.

# File I/O

Files may be opened with open(). This call returns an integer, which may be then bound as a file descriptor. C functions such as write(), read(), or lseek() may then be called on the file descriptor.

- open(filename, fd, fd2): opens a file. filename is a string referring to a file to be opened. Fd and fd2 are file descriptors used for open.
- write(fd, text, length): writes to a file. fd refers to the file descriptor of an open file. text is a string representing text to be written. length is an integer specifying the number of bytes to be written.

- read(fd, buf, length): reads from a file. fd refers to the file descriptor of an open file. buf is a pointer to malloc'd or allocated space. length is an integer representing amount of data to be read. Buffers should be malloc'd before reading.
- lseek(fd, offset, whence): sets a file descriptors cursor position. fd is the file descriptor to an open file. offset is an integer describing how many bytes the cursor should be offset by, and whence is an integer describing how offset should be applied: as an absolute location, relative location to the current cursor, or relative location to the end of the file.

For more detailed information on these calls, run man function\_name.

```
function main() int{

let fd int;
let malloced string;
fd = open("tests/HELLO00000.txt", 66, 384); /* Open this file */
write(fd, "hellooo!\n", 9); /* Write these 9 bytes */
malloced = malloc(10); /* Allocate space for the data and null terminator */
lseek(fd, 0, 0); /* Jump to the front of the file */
read(fd, malloced, 10); /* Read the data we just wrote into the buffer */
print(malloced); /* Prints "hellooo!\n" */
return 0;
}
```

#### Sockets API

# 3. Language Reference

# 3.1 Data types

## **Primitive Types**

#### int

A standard 32-bit two's-complement signed integer. It can take any value in the inclusive range (-2147483648, 2147483647).

#### boolean

A 1-bit true or false value.

## Complex Types

### string

An immutable array of characters, implemented as a native data type in Democritus.

#### struct

A struct is a simple user-defined data structure that holds various primitives, similar to the ones found in C.

## 3.2 Lexical Conventions

In this subsection, we will cover the standard lexical conventions for Democritus. As with languages such as C, Algol, or Pascal, Democritus is a free-format language. The parser will discard whitespace characters such as ',  $\t$ , and  $\n$ .

## **Identifiers**

Identifiers for Democritus will be defined as follows: any sequence of letters and numbers without whitespaces and is not a keyword will be parsed as an identifier. Note that, as in other languages, identifiers cannot begin with a number. Somewhat different, however, is the order of variable declarations; in Democritus, declarations are made following the *varname vartype* structure. The regular expression defining identifiers is as follows:

```
['a'-'z' 'A'-'Z']['a'-'z' 'A'-'Z' '0'-'9' '_']*
```

An example of declarations with identifiers:

```
2wrongID int;  /* not a valid identifier declaration */
mySecond float;  /* valid */
my_Second char;  /* valid */
```

### Literals

Literals, simply a sequence of numbers, may be identified with the regular expression

```
['0'-'9']+ (* Int *)
['0'-'9']*'.'['0'-'9']+ (* Float *)
```

### **Tokens**

The list of tokens used in Democritus are as follows:

```
{ LPAREN
')'
           RPAREN
'{'
           LBRACE
'}'
           RBRACE }
';'
          { SEMI }
' : '
          { COLON }
         { COMMA }
' +'
         { PLUS }
'_'
          { MINUS }
' *'
          { TIMES }
। %।
          { MOD }
">>"
          { RSHIFT
"<<"
          { LSHIFT
'/'
          { DIVIDE
' = '
          { ASSIGN }
"=="
         { EQ }
"!="
         { NEQ }
'<'
         { LT }
         { LEQ }
"<="
">"
          { GT }
">="
         { GEQ }
" & & "
          { AND }
" || "
          { OR }
" | "
         { NOT }
"if"
         { IF }
"else"
         { ELSE }
"elif"
         { ELIF }
"for"
          { FOR }
"return" { RETURN }
"int"
          { INT }
"float" { FLOAT }
"char"
         { CHAR }
"boolean"
            { BOOLEAN }
'*' { POINTER }
'&' { AMPERSAND }
"function" { FUNCTION }
"void" { VOID }
"struct" { STRUCT }
"string" { STRING }
"true"
         { TRUE }
"false" { FALSE }
"break" { BREAK }
"continue" { CONTINUE }
"atomic" { ATOMIC }
```

These words have been reserved by the compiler and hold special meaning within the language. Though most are self-explanatory, we will delve into their usage later on.

### **Punctuation**

#### Semicolon

As in C, the semicolon ';' is required to terminate any statement in Democritus.

statement SEMI

### **Curly Brackets**

In order to keep the language free-format, curly braces are used to delineate separate and nested blocks. These braces are required even for single-statement conditional and iteration loops.

LBRACE statements RBRACE

#### Parentheses

To assert precedence, expressions may be encapsulated within parentheses to guarantee order of operations.

LPAREN expression RPAREN

#### Comments

For now, comments are initiated with /\* and closed with \*/. They cannot be nested.

# 3.3 Expressions and Operators

An expression consists of a combination of any of the following:

- a literal value
- a variable name
- a binary operation
- a unary operation
- an array access operation
- a struct access

### **Declaration and Assignment**

Democritus requires all named variables to be declared with its type at the top of each function. Named variables are declared with the let [ID] type syntax. Assignment to these variables may be done with =.

```
x float = 4.0;
y int = 5/2 + 1; /* y = 3 */
```

Array assignment is done with Java-like syntax. Note that the size of the array must be specified in the declaration.

```
x int[5] = \{0,1,2,3,4\};
```

Pointer types are denoted with a \* which must be attached to the primitive type that they reference.

```
x int = 4;  /* x = 4 */
y int* = &x;  /* *y = 4 */
```

## **Arithmetic Operations**

Democritus supports all the arithmetic operations standard to most general-purpose languages like C and Java. Note that casting is not built into the language; this functionality will instead be implemented through the standard library.

#### **Addition and Subtraction**

Addition works with the + character, behaving as expected.

```
x int = 4;
y int = 2;
x = x + y;  /* x = 6 */
y = y - x  /* y = -4 */
```

### Multiplication

Multiplication follows the same rules as well.

```
x int = 4;
y int = 2;
x = x * y + y; /* x = 10 */
```

#### Division

Democritus will default to integer division, unless both types provided are floats.

```
x int = 5;
y int = 2;
x = x / y; /* x = 2 */
a float = 4.0;
b float = 2.0;
a = b / a; /* a = 2.0 approximately */
```

#### Modulus

The remainder of an integer division operation can be computed via the modulo % operator.

```
x int = 8;
y int = 5;
x = x%y; /* x = 3 */
```

### **Bit Shifting**

Integers can be bit-shifted with >> and <<.

```
x int = 9;
y int = x>>1; /* y = 4 */
x = y<<2; /* x = 16 */
```

### Boolean Expressions

Democritus features all of the standard logical operators, following Java-style syntax. Each expression will return a boolean value of true or false.

### **Equality**

Equality is tested with the == operator. Inequality is tested with !=.

```
x int = 8;
y int = 8;
z boolean = (x == y);  /* z = true */
z = (x == (y + 1));  /* z = false */
z = (x != (y + 1));  /* z = true */
```

### Negation

Negation is done with !, a unary operation.

### Comparison

Democritus also features the <, <=, >, and >= operators.

```
x int = 9;
y int = 8;
z int = 8;

x>y;  /* true */
y>=z;  /* true */
z<x;  /* true */</pre>
```

### **Chained Expressions**

Boolean expressions can be chained with && and ||, representing and or, respectively. These operators have lower precedence than any of the other boolean operators described above. The and operator has a higher precedence than or.

```
x int = 9;
y int = 8;
z int = 8;

(x>y && y<x);    /* false */
(x>y || y<x);    /* true */
(x>y && y<x || z==y)    /* true */</pre>
```

### Pointers and References

Pointers and dereferencing operations utilize the same syntax as C. The unary operator & gives a variables address in memory, and the operator \* dereferences a pointer. See the assignment subsection for usage.

### Array access

Array access is done with [i] where i is the index being accessed.

```
x int[5] = {0,1,2,3,4};
y int = x[2];  /* y = 2 */
```

# Operator Precedence and Associativity

Precedence	Operator	Description	Associativity
1	()	Parenthesis	Left-to-right
2	()	Function call	Left-to-right
	{}	Array creation s	
	[]	Array subscript	
3	*	Dereference	Right-to-left
	&	Address-of	
	!	Negation	
	_	Unary minus	
4	*	Multiplication	Left-to-right
	/	Division	
	%	Modulo	
5	+	Addition	Left-to-right
	-	Subtraction	
6	>>	Bitwise shift shift right	Left-to-right
	<<	Bitwise shift left	
7	>> =	For relational $>$ and $\ge$ respectively	Left-to-right
	<<=	For relational $<$ and $\le$ respectively	
8	== !=	For relational = and $\neq$ respectively	Left-to-right
9	&&	Logical and	Left-to-right
10		Logical or	Left-to-right
11	=	Assignment	Right-to-left

# 3.4 Statements

## **Expressions**

An expression statement consists of an expression followed by a semicolon. Expressions in expression statements will be evaluated, and its value calculated.

```
a int = 500;
s char = 'a';
2 + 4 - 3;  /* Not used, thrown away */
```

### **Declarations**

A declaration specifies a variable's name and type, in that order. Values may also be initialized in the declaration.

```
x int;
y char = '4';
```

## **Control Flow**

```
if, elif, else
```

An if statement causes a block (encapsulated by  $\{$  and $\}$ ) to be entered if the specified condition evaluates to true.

An elif allows an alternate condition to be specified.

An else is entered if the 'if' and 'elif's are not entered.

A boolean expression encapsulated within parentheses is required for every if and elif. Elif and else belong to the first preceding if statement.

```
x int = 1;
if (x == 1)
{
    print("x==1!");
}
elif (x == 2)
{
    print("x==2!");
}
else
{
    print("fail");
}
```

### Looping with for

Democritus eliminates the while structure, replacing it instead with a modified for loop. For can be used to iterate by providing an initialization, termination condition, and update:

```
for(i int = 0; i < 10; i++)
{
    /* Some code here */
}</pre>
```

It can also be used as a while loop providing only one condition:

```
for(x < 10)
{
    /* Some code here */
}</pre>
```

### 3.5 Functions

### Overview

Functions can be defined in Democritus to return one or no data type. Functions are evaluated via eager evaluation and the function implementation must directly follow the function header. The syntax is reminiscent of Scala, although Democritus doesn't support implied returns. A function appears in the form:

```
function [function name]([formal_arg type, ...]) type {
    [function implementation]
    return [variable of return type]
}
```

**Note**: all functions need return statements at the end (no falling off the end). A void return is simply a return with nothing following it.

Functions may be recursive and call themselves:

```
function recursive_func(i int) void {
    if (i < 0) {
        return;
    } else {
        print h i ;
        recursive_fun(i-1);
    }
}</pre>
```

Functions may be called within other functions:

```
function main() void{
   recursive_func(3);
   return;
}
```

#### **Built-in Functions**

A handful of functions are natively built into Democritus for user flexibility and ease of usage. There are:

- print(s string) takes in a string (standard library functions will convert from other data types to strings)
- thread(f function, [arg1 type, arg2 type, ...]) takes in function and function args

# 3.6 Concurrency

### Overview

Democritus intends to cater to modern software engineering use cases. Developments in the field are steering us more and more towards highly concurrent programming as the scale at which software is used trends upward.

With this in mind, Democritus adds support for the atomic keyword, used as a modifier at the declaration step. The keyword can be used both in an inline declaration and when declaring a function's types. We also wrap the  $pthread_t$  datatype and related functions.

#### Atomic Inline Declarations

Under the hood, declaring a variable with the atomic keyword embeds a locking structure into the type, as well as exposing the lock() and unlock() functions. If the keyword is used with a standard data type, the compiler replaces the normal version of that type with a version that includes the lock and the functions described above.

```
x int;
x.lock(); x.unlock(); /* undefined! */

y atomic int;
y.lock(); y.unlock(); /* defined! */

}
```

### **Atomic Parameter Declarations**

A function whose formal parameters are atomic will throw a compile-time error if a non-atomic type is passed in. The idea is to force the programmer to document which functions are safe to use in a multi-threaded context and which are not.

```
function [function name]([formal_arg atomic type]) atomic type {
  formal_arg.lock();
  /* do something */
  formal_arg.unlock();
  return formaL_arg
}
```

Naturally, rather than calling lock() and unlock() manually, the programmer can implement atomic operations.

## **Spawning Threads**

To spawn threads, Democritus uses a wrapper around the C-language pthread family of functions.

The  $thread_t$  data type wraps  $pthread_t$ .

To spawn a thread, the thread function takes a variable number of arguments where the first argument is a function and the remaining optional arguments are the arguments for that function. It returns an error code.

The detach boolean determines whether or not the parent thread will be able to join on the thread or not.

```
{
  thread(f function, boolean detach, [arg1 type, arg2 type, ...]) int;
}
```

# 4. Project Plan

- 4.1 Workflow
- 4.2 Team Member Responsibilities
- 4.3 Git Logs

# 5. Architecture Overview

Democritus' compiler is built off of Professor Stephen Edwards' MicroC compiler.

# 5.1 Compiler Overview

Several files make up the source code of the compiler.

### The Scanner

The scanner is simply a text scanner that parses text into various tokens, to then be interpreted by the parser. The regular expressions used by the scanner were listed above in the language reference chapter.

### The Parser

The parser is a token scanner that converts the tokens read into a valid abstract syntax tree of the program. If the program follows valid syntax, it will be parsed accordingly. Otherwise, compilation of code will yield a parse error. The structure of the program is as follows:

The Semantic Analyzer

The Code Generator

# 5.2 C Bindings

pthread()

sockets API

File I/O

# 6. Testing

6.1 Integration Testing

Aside: Unit Testing

6.2 The Test Suite and Automated Regression Testing
