# 1. Introduction

Democritus is a programming language with a static type system and native support for concurrent programming via its atomic keyword, with facilities for both imperative and functional programming. Democritus is compiled to the LLVM (Low Level Virtual Machine) intermediate form, which can then be optimized to machine-specific assembly code. Democritus' syntax draws inspiration from contemporary languages, aspiring to emulate Go and Python in terms of focusing on use cases familiar to the modern software engineer, emphasizing readability, and having "one – and preferably only one – obvious way to do it".

# 1.1 Motivation

The main motivation behind Democritus was to create a lower level imperative language that supported concurrency 'out-of-the-box'. The race condition arising from threading would be solved by the language's atomic keyword, which provides a native locking system for variables and data. Users would then be able to write and run simple multi-threaded applications relatively quickly.

# 1.2 Product Goals

## **Native Concurrency and Atomicity**

Users should be able to easily and quickly thread their program with minimal worry about race conditions. Their development process should not be hindered by the use of multithreading, nor should they have to define special threading classes as is common in some other languages.

#### Portability

Developed under the LLVM IR, code written in Democritus can be compiled and run on any machine that LLVM can run on. As an industrial-level compiler, LLVM offers robustness and portability as the compiler back-end of Democritus.

# Flexibility

Though Democritus is not an object-oriented language, it seeks to grant users flexibility in functionality, supporting structures, standard primitive data types, and native string support.

<sup>&</sup>lt;sup>1</sup>http://c2.com/cgi/wiki?PythonPhilosophy

# 2. Language Tutorial

Democritus is a statically-typed, imperative language with standard methods for conditional blocks, iteration, variable assignment, and expression evaluation. In this chapter, we will cover environment configuration as well as utilizing bothDemocritus' basic and advanced features.

# 2.1 Setup and Installation

To set up the Democritus compiler, OCaml and LLVM must be installed. Testing and development was done in both native Ubuntu 15.04 and Ubuntu 14.04 running on a virtual machine.

```
sudo apt-get install m4 clang-3.7 clang clang-3.7-doc libclang-common-3.7-dev libclang -3.7-dev libclang1-3.7 libclang1-3.7-dbg libllvm-3.7-ocaml-dev libllvm3.7 libllvm3.7-dbg lldb-3.7 llvm-3.7 llvm-3.7-dev llvm-3.7-doc llvm-3.7-examples llvm-3.7-runtime clang-modernize-3.7 clang-format-3.7 python-clang-3.7 lldb-3.7-dev liblldb -3.7-dbg opam llvm-runtime
```

For Ubuntu 15.04, we need the matching LLVM 3.6 OCaml Library.

```
sudo apt-get install -y ocaml m4 llvm opam
opam init
opam install llvm.3.6 ocamlfind
eval 'opam config env'
```

#### For Ubuntu 14.04:

```
sudo apt-get install m4 llvm software-properties-common

sudo add-apt-repository —yes ppa:avsm/ppa
sudo apt-get update -qq
sudo apt-get install -y opam
opam init

eval 'opam config env'

opam install llvm.3.4 ocamlfind
```

After setting up the environment, clone the git repository into your desired installation directory:

```
git clone https://github.com/DemocritusLang/Democritus.git
```

# 2.2 Compiling Your Code

To build the compiler, cd into the Democritus repository, and run make.

If building fails, try running eval 'opam config env', which should update your local environment use OPAM packages and compilers. It's recommended to add the above command to your shell's configuration file if you plan on developing with Democritus.

To compile code, simply run

```
./Democritus < filename.dem > outfile.lli
```

To run compiled code, call 11i on the output:

```
lli outfile.lli
```

# 2.3 Writing Code

Code can be written in any text file, but Democritus source files should have the .dem extension by convention. Democritus programs consist of global function, struct, and variable declarations. Only the code inside main() will be exectued at runtime. At this time, linking is not included in the Democritus compiler; all code should be written and compiled from a single .dem source file.

# 2.4 Getting Started

#### **Declarations**

Functions are declared with the <function func\_name(a type, b type) return\_type> syntax. Variables are declared with the <let var\_name var\_type;> syntax. Statements are terminated with the semicolon;. Note that all variable declarations must happen before statements (including assignments) in any given function.

```
function triangle_area(base int, height int) int{
  return base*height/2;
}
```

# **Types**

#### **Primitives**

Primitive types in Democritus include booleans and integers. The void type is also used for functions.

#### Strings

Strings are built-in to Democritus. String literals are added to global static memory at runtime, and string variables point to the literals. These literals are automatically null-terminated.

```
function main() int{
  let s string;
  let foo int;
  let bar bool;

bar = true;
  s = "Hello, World!"
  foo = 55;
  bar = false;

return 0;
}
```

#### Structs

Structs are declared at the global level with the <struct struct\_type { named fields }> syntax. Struct declarations may also be nested.

```
struct Person{
 let name string;
 let age int;
 let info struct Info;
struct Info{
 let education string;
 let salary int;
function main() int{
  let p struct Person;
  p.name = "Joe";
  p.age = 30;
  p.info.education = "Bachelor's";
  p.info.salary = 99999;
  print(p.name);
  print(" earns: ");
  print_int(p.info.salary);
  return 0;
```

### **Operators**

Democritus includes the 'standard' set of operators, defined as follows:

# **Binary Operators:**

```
artithmetic: +, -, *, /, %
logical: ==, !=, <, <=, >, >=, && (and), || (or)
```

# **Unary Operators:**

```
artihmetic: -logical: ! (not)addressing: & (reference), * (reference)
```

Logical expressions return a boolean value.

The expressions on each side of a binary operation must be of the same type. The &&, ||, and ! operators must be called on boolean expressions.

References can only be called on addressable fields (such as variables, or struct fields). Dereferences can only be called on pointer types.

# 2.5 Pointers

# 2.6 Control Flow

As an imperative language, Democritus executes statements sequentially from the top of any given function to the bottom. Branching and iteration is done similarly to many other imperative languages.

# **Conditional Branching**

Conditional branching is done with:

```
if(boolean expression)
{
    /* do something here */
}
else
{
    /* do alternative here */
}
```

Here is an example of conditional branching in Democritus:

```
struct Person{
  let education string;
  let name string;
  let age int;
  let working bool;
function main() int{
  let p Struct person;
  p.name = "Joe"
  p.education = "Bachelor's";
  p.age = 25;
  p.working = false;
  if (p.working) {
    print(p.name);
   print(" works.\n");
  }else{
   print(p.name);
   print(" is looking for work.\n");
 return 0;
```

This program prints "Joe is looking for work."

# Loops and Iteration

Iteration can be done either via a for loop. A for(e1; e2; e3) loop may take three expressions; e1 is called prior to entering the loop, e2 is a boolean conditional statement for the loop, and e3 is called after

each iteration. Both e1 and e3 are optional; omitting both converts the for loop into the conditional while used in other languages.

```
function main() int{
  let i int;
  for(i = 0; i < 42; i++) {
     i = i+1;
  }

  for(; false;) {
     // This block will never be reached
  }

  for(true) {
     print_int(i);
  }
  return 0;
}</pre>
```

This program will print 42 forever.

# 2.7 Multithreading and Atomicity

Democritus supports threading with the thread() function call, which then calls the underlying pthread function in C. Any defined function can be called with multiple threads. The calling syntax is as follows:

```
thread("functionname", <comma separated args>, #threads);
```

Multithreaded functions must take a starvoid type as input and return a starvoid to conform with C's calling convention. An example of a multithreaded program:

```
function multiprint(noop starvoid) starvoid{
  let x starvoid;
  print("Hello, World!\n");
  return x;
}

function main() int{
  thread("multiprint", 0, 6); /* "Hello, World!" will be printed six times. */
  return 0;
}
```

# 2.8 Miscellaneous

Besides threading, a couple of other functions from C have been bound to Democritus.

#### Malloc

malloc(size) may be called, returning a pointer to a newly heap-allocated block of *size* bytes. These pointers may be bound to strings, which themselves are pointers to string literals. An example utilizing malloc will be included with file I/O.

# File I/O

Files may be opened with open(). This call returns an integer, which may be then bound as a file descriptor. C functions such as write(), read(), or lseek() may then be called on the file descriptor.

- open(filename, fd, fd2): opens a file. filename is a string referring to a file to be opened. Fd and fd2 are file descriptors used for open.
- write(fd, text, length): writes to a file. fd refers to the file descriptor of an open file. text is a string representing text to be written. length is an integer specifying the number of bytes to be written.
- read(fd, buf, length): reads from a file. fd refers to the file descriptor of an open file. buf is a pointer to malloc'd or allocated space. length is an integer representing amount of data to be read. Buffers should be malloc'd before reading.
- lseek(fd, offset, whence): sets a file descriptors cursor position. fd is the file descriptor to an open file. offset is an integer describing how many bytes the cursor should be offset by, and whence is an integer describing how offset should be applied: as an absolute location, relative location to the current cursor, or relative location to the end of the file.

For more detailed information on these calls, run man function\_name.

```
function main() int{
  let fd int;
  let malloced string;

fd = open("tests/HELLOOOOOO.txt", 66, 384);  /* Open this file */
  write(fd, "hellooo!\n", 10);  /* Write these 10 bytes */

malloced = malloc(10);  /* Allocate space for the data and null terminator */
  lseek(fd, 0, 0);  /* Jump to the front of the file */
  read(fd, malloced, 10);  /* Read the data we just wrote into the buffer */

  print(malloced);  /* Prints "hellooo!\n" */
  return 0;
}
```

# Sockets API

# 3. Language Reference Manual

# 3.1 Introduction

In the grammars shown in this reference manual, all terminals are expressed in uppercase and all nonterminals are kept lowercase. The Lexical Conventions section will detail terminals (also known as tokens).

# 3.2 Structure of a Democritus Program

The full grammar of a program is as follows:

```
program:
  decls EOF
decls:
   /* nothing */
 | decls vdecl
 | decls fdecl
 | decls sdecl
fdecl:

```

# 3.3 Data types

# **Primitive Types**

#### int

A standard 32-bit two's-complement signed integer. It can take any value in the inclusive range (-2147483648, 2147483647).

#### boolean

A 1-bit true or false value.

#### pointer

A 64-bit pointer that holds the value to a location in memory; pointers may be passed and dereferenced.

# Complex Types

#### string

An immutable array of characters, implemented as a native data type in Democritus.

#### struct

A struct is a simple user-defined data structure that holds various data types, such as primitives, other structs, or pointers.

# 3.4 Lexical Conventions

In this subsection, we will cover the standard lexical conventions for Democritus. Lexical elements are scanned as 'tokens,' which are then parsed into a valid Democritus program. Democritus is a free-format language, discarding all whitespace characters such as '',  $\t$ , and  $\n$ .

### **Identifiers**

Identifiers for Democritus will be defined as follows: any sequence of letters and numbers without whitespaces and not a keyword will be parsed as an identifier. Identifiers must start with a letter, but they may contain any lowercase or uppercase ASCII letter, numbers, and the underscore '\_'. Identifiers are case-sensitive, so 'var1' and 'Var1' would be deemed separate and unique. Identifiers are used to identify named elements, such as variables, struct fields, and functions. Note that identifiers cannot begin with a number. The following is a regular expression for identifiers:

```
ID = "['a'-'z' 'A'-'Z']['a'-'z' 'A'-'Z' '0'-'9' ']*"
```

## Reserved Keywords

The following is a list of reserved Democritus keywords:

if	else	for	return	int
bool	void	true	false	string
struct	*void	function	let	

#### Literals

Literals are used to represent various values or constants within the language.

#### **Integer Literals**

Integer literals are simply a sequence of ASCII digits, represented in decimal.

```
INT = "['0'-'9']+"
```

#### **Boolean Literals**

Boolean literals represent the two possible values that boolean variables can take, true or false. These literals are represented in lowercase.

```
BOOLEAN = "true|false"
```

#### String Literals

String literals represent strings of characters, including escaped characters. String literals are automatically null-terminated. Strings are opened and closed with double quotations. A special OCaml lexbuf was used to parse string literals.

(Taken from http://realworldocaml.org/v1/en/html/parsing-with-ocamllex-and-menhir.html)

```
read_string buf = parse
```

#### All Democritus Tokens

The list of tokens used in Democritus are as follows:

```
| "//"
            { comment lexbuf }
| "/*"
            { multicomment lexbuf }
| '('
            { LPAREN }
| ')'
            { RPAREN }
| '{'
            { LBRACE }
| '}'
            { RBRACE }
1 ';'
            { SEMI }
            { COMMA }
| '+'
            { PLUS }
| '-'
            { MINUS }
| '*'
            { STAR }
1 '&'
            { REF }
 , ,
            { DOT }
| '/'
            { DIVIDE }
 ,=,
            { ASSIGN }
 "=="
            { EQ }
 "!="
            { NEQ }
| '<'
            { LT }
| "<="
            { LEQ }
| ">"
            { GT }
 ">="
           { GEQ }
| "&&"
            { AND }
| "||"
            { OR }
1 "!"
            { NOT }
| "if"
            { IF }
| "else"
            { ELSE }
| "for"
            { FOR }
| "return" { RETURN }
| "int"
           { INT }
| "bool"
           { BOOL }
| "void"
            { VOID }
| "true"
            { TRUE }
| "string" { STRTYPE }
| "struct" { STRUCT }
           { VOIDSTAR }
| "*void"
| "false"
           { FALSE }
| "function" { FUNCTION }
| "let"
              { LET }
| ['0'-'9']+ as lxm { LITERAL(int_of_string lxm) }
| ['a'-'z' 'A'-'Z']['a'-'z' 'A'-'Z' '0'-'9' '_']* as lxm { ID(1xm) }
         { read_string (Buffer.create 17) lexbuf } (* refer to read_string above *)
| eof { EOF }
```

### **Punctuation**

#### Semicolon

The semicolon ';' is required to terminate any statement in Democritus.

```
statement SEMI
```

### **Curly Brackets**

In order to keep the language free-format, curly braces are used to delineate separate and nested blocks. These braces are required even for single-statement conditional and iteration loops.

LBRACE statements RBRACE

#### **Parentheses**

To assert precedence, expressions may be encapsulated within parentheses to guarantee order of operations.

LPAREN expression RPAREN

#### Comments

Comments may either be single-line, intialized with two backslashes, or multi-line, enclosed by \\* and \*\.

```
COMMENT = ("// [^'\n']* \n") | ("/*" [^ "*/"]* "*/")
```

# 3.5 Variable Declarations

In Democritus, local variables must be declared at the top of each function, before being later assigned.

#### Variable Declaration

Democritus requires all named variables to be declared with its type at the top of each function. Named variables are declared with the let [ID] type syntax. Assignment to these variables may then be done with =.

The grammar for variable declarations is as follows:

```
vdecl:
LET ID typ SEMI

typ:
INT
| BOOL
| VOID
| STRTYPE
| STRUCT ID
| VOIDSTAR
| STAR %prec POINTER typ
```

### Struct Declaration

Structs are defined at the global scope, and can then be declared as variables. The global definitions are as follows:

#### sdecl:

STRUCT ID LBRACE vdecl\_list RBRACE

vdecl\_list:

| vdecl\_list vdecl

# 3.6 Expressions and Operators

## **Expressions**

Expressions may be any of the following:

#### Literal

A literal of any type, as detailed in the lexical conventions section.

#### Identifier

An identifier for a variable.

#### **Binary Operation**

A binary operation between an expression and another expression.

#### **Unary Operation**

A unary operation acting on the expression appearing on the immediate right of the operator.

#### Struct Access

An expression of a struct type accessing an identifier field with the dot (.) operator.

## Struct Assignment

An expression of a struct type assigning a value to one of its fields (accessed with the dot (.) operator) using the = operator.

## **Function Call**

A call to a function along with its formal arguments.

# Variable Assignment

An identifier being assigned a value with the = operator.

#### Parenthisization

Another expression nested within parentheses.

The grammar for expressions is as follows:

```
expr:
   LITERAL
  | FLOATLITERAL
  | TRUE
  | FALSE
  | ID
  | STRING
  | expr PLUS
                                  (* expr TERMINAL expr are binary operations *)
                expr
  | expr MINUS expr
  | expr STAR
                expr
  | expr DIVIDE expr
  | expr MOD
                expr
  | expr EQ
                expr
  | expr NEQ
                expr
  expr LT
                expr
  | expr LEQ
                expr
  | expr GT
                expr
  | expr GEQ
                expr
  | expr AND
                expr
  | expr OR
                expr
                                  (* struct acccess
  | expr DOT
               ID
                                                        *)
  | expr DOT
               ID ASSIGN expr
                                  (* struct assign
                                                        *)
  | MINUS expr %prec NEG
                                  (* unary arith negate *)
               %prec DEREF
  | STAR expr
                                  (* unary deref
                                                        *)
  | REF expr
                                  (* unary ref
                                                        *)
                                  (* unary log negate
  | NOT expr
                                                        *)
  | ID ASSIGN expr
  | ID LPAREN actuals_opt RPAREN (* function call
                                                        *)
  | LPAREN expr RPAREN
                                  (* paren'd expr
                                                        *)
```

## Binary and Unary Operations

A binary operation operates on the two expressions on the left and right side of the operator. Binary operations may be:

- an addition, subtraction, mult., division, or modulo on two arithmetic expressions (+,-,\*,/,%). Modulo only works on integer types.
- equality or inequality expression between boolean expressions (==,!=,<,<=,>,>=,&&,||)

A unary operation operates on the expression on the operator's right side:

- a negation of an arithmetic expression (-)
- a dereference of a pointer type (\*)
- an address reference of a variable or field within a struct (&)
- a negation of a boolean expression (!)

# **Arithmetic Operations**

Democritus supports all the arithmetic operations standard to most general-purpose languages, documented below. Automatic casting has not been included in the language, and the compiler will throw an error in the case that arithmetic operations are performed between the same types of expressions.

#### Addition and Subtraction

Addition works with the + character, behaving as expected. Subtraction is called with -.

## Multiplication and Division

Multiplication is called with \*, and division with /. Division between integers discards the fractional part of the division.

#### Modulo

The remainder of an integer division operation can be computed via the modulo % operator.

# Boolean Expressions

Democritus features all standard logical operators, utilizing ! for negation, and && and || for and and or, respectively. Each expression will return a boolean value of true or false.

#### **Equality**

Equality is tested with the == operator. Inequality is tested with !=. Equality may be tested on both boolean and arithmetic expressions.

# Negation

Negation is done with !, a unary operation for boolean expressions.

### Comparison

Democritus also features the <, <=, >, and >= operators. These represent less than, less than or equal to, greater than, and greater than or equal to, respectively. These operators are called on arithmetic expressions and return a boolean value.

#### Chained Expressions

Boolean expressions can be chained with && and ||, representing and or. These operators have lower precedence than any of the other boolean operators described above. The and operator has a higher precedence than or.

### **Parentheses**

Parentheses are used to group expressions together, since they have the highest order of precedence. Using parentheses will ensure that whatever is encapsulated within will be evaluated first.

# **Function Calls**

Function calls are treated as expressions with a type equal to their return type. As an applicative-order language, Democritus evaluates function arguments first before passing them to the function. The grammar for function calls is as follows:

```
expr:
    .
    .
    .
        ID LPAREN actuals_opt RPAREN (* Function call *)

actuals_opt:
    /* nothing *?
    | actuals_list

actuals_list:
    expr
    | actuals_list COMMA expr
```

### Pointers and References

Referencing and dereferencing operations are used to manage memory and addressing in Democritus. The unary operator & gives a variable or struct field's address in memory, and the operator \* dereferences a pointer type.

# Operator Precedence and Associativity

Precedence	Operator	Description	Associativity
1	()	Parenthesis	Left-to-right
2	()	Function call	Left-to-right
3	*	Dereference	Right-to-left
	&	Address-of	
	į.	Negation	
	_	Unary minus	
4	*	Multiplication	Left-to-right
	/	Division	
	%	Modulo	
5	+	Addition	Left-to-right
	_	Subtraction	
6	>> =	For relational $>$ and $\ge$ respectively	Left-to-right
	<<=	For relational $<$ and $\le$ respectively	
7	== !=	For relational = and $\neq$ respectively	Left-to-right
8	&&	Logical and	Left-to-right
9	11	Logical or	Left-to-right
10	=	Assignment	Right-to-left

# 3.7 Statements

Statements written in a Democritus program are run from the top to bottom, sequentially. Statements can reduce to the following:

# Expressions

An expression statement consists of an expression followed by a semicolon. Expressions in expression statements will be evaluated, with their values calculated.

#### Return Statements

A return statement is either a RETURN SEMI or RETURN expr SEMI. They are used as endpoints of a function, and control from a function returns to the original caller when a return statement is executed. Returns may be empty or return a type, though non-void functions must return an expression of their type.

#### **Nested Blocks**

A nested block is another statement list encapsulated within braces {}.

#### Conditional Statements

Conditional statements follow the IF (boolean expr) stmt1 ELSE stmt2 format. When the expr evaluates to true, stmt1 is run. Otherwise, if an ELSE and stmt2 have been specified, stmt2 is run.

## Conditional Loops

A conditional loop is similar to a conditional statement, except in that it will loop or run repeatedly until its given boolean expression evaluates to false. In the case that the expression never evaluates to false, an infinite loop will occur.

Democritus eliminates the while keyword sometimes used in conditional iteration. Conditional loops follow the FOR (expr1;boolean expr2;expr3) stmt format where expr1 and expr3 are optional expressions to be evaluated prior to entering the for loop and upon each loop completion, respectively. Prior to entering or re-entering the loop, expr2 is evaluated; control only transfers to stmt if this evaluation returns true. If both expr1 and expr3 are omitted, a simpler for loop can be written of the form FOR (boolean expr) stmt.

The full gammar for statements is as follows:

```
stmt_list:
    /* nothing */
    | stmt_list stmt

stmt:
    expr SEMI
    RETURN SEMI
    RETURN expr SEMI
    RETURN expr SEMI
    I LBRACE stmt_list RBRACE
    I IF LPAREN expr RPAREN stmt %prec NOELSE
    I IF LPAREN expr RPAREN stmt ELSE stmt
    FOR LPAREN expr_opt SEMI expr_opt RPAREN stmt
    FOR LPAREN expr RPAREN stmt
```

# 3.8 Functions

### Overview and Grammar

Functions can be defined in Democritus to return one or no data type. Functions are evaluated via eager (applicative-order) evaluation and the function implementation must directly follow the function header. The grammar for function declarations is as follows:

#### fdecl:

FUNCTION ID LPAREN formals\_opt RPAREN typ LBRACE vdecl\_list stmt\_list RBRACE

```
formals_opt:
    /* nothing */
    | formal_list

formal_list:
    ID typ
    | formal_list COMMA ID typ
```

All functions require return statements at the end, and must return an expression of the same type as the function. void functions may simply terminate with an empty return statement.

```
}
function function_name([formal_arg type, ...]) type_r {

    [function implementation]
    return [variable of type type_r]
}
```

# Calling and Recursion

Functions may be recursive and call themselves:

```
function recursive_func(i int) void {

   if (i < 0) {
      return;
   } else {
      print( h i );
      recursive_func(i-1); // Call ourselves again.
   }
}</pre>
```

Functions may be called within other functions:

# 3.9 Concurrency

#### Overview

Democritus intends to cater to modern software engineering use cases. Developments in the field are steering us more and more towards highly concurrent programming as the scale at which software is used trends upward.

With this in mind, Democritus adds support for the atomic keyword, used as a modifier at the declaration step. The keyword can be used both in an inline declaration and when declaring a function's types. We also wrap the  $pthread_t$  datatype and related functions.

### **Atomic Inline Declarations**

Under the hood, declaring a variable with the atomic keyword embeds a locking structure into the type, as well as exposing the lock() and unlock() functions. If the keyword is used with a standard data type, the compiler replaces the normal version of that type with a version that includes the lock and the functions described above.

```
}
  x int;
  x.lock(); x.unlock(); /* undefined! */

y atomic int;
  y.lock(); y.unlock(); /* defined! */
}
```

#### **Atomic Parameter Declarations**

A function whose formal parameters are atomic will throw a compile-time error if a non-atomic type is passed in. The idea is to force the programmer to document which functions are safe to use in a multi-threaded context and which are not.

```
function [function name]([formal_arg atomic type]) atomic type {
  formal_arg.lock();
  /* do something */
  formal_arg.unlock();
  return formaL_arg
}
```

Naturally, rather than calling lock() and unlock() manually, the programmer can implement atomic operations.

### Spawning Threads

To spawn threads, Democritus uses a wrapper around the C-language pthread family of functions. The  $thread_t$  data type wraps  $pthread_t$ .

To spawn a thread, the thread function takes a variable number of arguments where the first argument is a function and the remaining optional arguments are the arguments for that function. It returns an error code.

The detach boolean determines whether or not the parent thread will be able to join on the thread or not.

```
{
  thread(f function, boolean detach, [arg1 type, arg2 type, ...]) int;
}
```

# 4. Project Plan

# 4.1 Planning

Much of the planning was facilitated by our weekly meetings with David Watkins, our TA. He very clearly explained what the requirements of each milestone entailed, and helped keep expectations transparent. Since Professor Edwards had emphasized the need for vertical development of features instead of horizontal building of each compiler layer, we quickly identified the key features that would be required to enable the key functionality of our language. Two of the most important components were structs and threads.

Our initial plan, which we largely followed, was to complete the Language Reference Manual, experiment with the layers of the compiler and get Hello, World! working, and then use what we had learned to begin implementing the more crucial aspects of the language.

# 4.2 Workflow

Workflow was facilitated by Git and GitHub, which allowed for the team to easily work on multiple features simultaneously and (usually) merge together features without overlapping conflicts. The Git workflow reached an optimal point by the conclusion of the project; new features would be developed, tested, and finalized in separate branches, and the commits for that feature would be squashed down until a single commit representing the new feature would be merged into the master branch.

Features were developed individually or through paired programming, depending on the scope and complexity of the feature. GitHub and division of labor allowed for many team members to work independently, at different times of the day per their own schedule. Branching allowed for one person to quickly deploy buggy code to another in hopes of resolving the issue, without any modification or bad commits to the master branch. GroupMe was used extensively for inter-team communication.

# 4.3 Team Member Responsibilities

Team Member	Responsibilities	GitHub Handle
Amy Xu	structs, nested structs, pointers	axxu
Emily Pakulski	C-bindings, reformatting tests, atomicity	ohEmily
Amarto Rajaram	C-bindings, pthread, file I/O, malloc	Amarto
Kyle Lee	structs, LRM, Final Report, debug and assist Amy	kyle–lee

# 4.4 Git Logs

# 5. Architecture Overview

Democritus' compiler is built off of Professor Stephen Edwards' MicroC compiler.

# 5.1 Compiler Overview

Several files make up the source code of the compiler. These include:

- scanner.mll: the OCamllex scanner.
- ast.ml: the abstract syntax tree, summarizing the overall structure of a Democritus program.
- parser.mly: the Ocamlyacc parser. Tokens from the scanner are parsed into the abstract syntax tree in the parser.
- semant.ml: the semantic analyzer.
- codegen.ml: the LLVM IR code generator.
- democritus.ml: the overarching OCaml program that calls the four main steps of the compiler.
- bindings.c: a C file that provides key underlying C functionality, such as for threads, which is compiled to LLVM bytecode.

# The Scanner

The scanner is simply a text scanner that parses text into various tokens, to then be interpreted by the parser. The regular expressions used by the scanner were listed above in the language reference chapter.

### The Parser

The parser is a token scanner that converts the tokens read into a valid abstract syntax tree of the program. If the program follows valid syntax, it will be parsed accordingly. Otherwise, compilation of code will yield a parse error. The structure of the program is as follows:

# The Semantic Analyzer

### The Code Generator

# 6. Testing

6.1 Integration Testing

Aside: Unit Testing

6.2 The Test Suite and Automated Regression Testing

# 7. Lessons Learned

- 7.1 Amy
- **7.2** Emily
- 7.3 Amarto
- **7.4** Kyle
